INTRODUCTION

This report presents updated population projections for Alberta for 1984-2011. These projections reflect the input of the inter-departmental sub-committee on Population Projections whose contribution is gratefully acknowledged.

The three projection series, Series A, B and C have incorporated recent declines in migration and a slight increase in fertility rates. Estimated fertility rates for 1983 are used as the fertility assumption and life table survival ratios for 1981 are used as the mortality assumption. These are employed for all the three series and are assumed to be constant throughout the projection period. Each series, however, employs a different migration assumption. For the short term, assumptions on interprovincial and international migration are derived from time series analysis of migration. Long term migration assumptions for all three series are derived based on variations of the low migration assumption used in the previous projection series. A description of the projection methodology is in the report: Population Projections, Alberta, 1982-2011, published in April 1983 by the Alberta Bureau of Statistics.

The new series are supplements to the previous population projections and are useful to readers whose needs for population information are for the short-term or whose concerns are the effects of different migration levels on the population characteristics in Alberta. The previous series are useful for long term planning purposes. They provide possible variations of future population growth in Alberta, although they do not capture the magnitude of recent changes in migration. Series A, B and C are similar to Series 1 and 2 of the previous projections and differ mainly due to the migration and fertility assumptions.

This report contains the highlights of the population projections update, a description of the assumptions used and detailed projection results by age and sex.

HIGHLIGHTS

Population growth rates for all three projection series are lower than those experienced in the recent past due to the lower migration levels used in the assumptions. In the early years, the number of out-migrants is assumed to be higher than that of in-migrants, resulting in a net loss through migration. Modest increases in the level of in-migration in later years will result in net migration ranging from 23,500 per year in Series A to 27,000 in Series C (Tables 4-6).

The population of Alberta is projected to grow from 2.36 million in 1983 to reach a range between 2.40 and 2.43 million by 1986 (Table 1). Population growth during the 1983-86 period is projected to range from an average of 11,000 per year to 23,000 per year, a substantial decline from the comparable figure of 62,000 recorded during 1981-83.

By the year 2011, Alberta's population is expected to reach 3.50 million using the migration assumptions of Series A. This represents an average annual growth rate of 1.4% over the 28 years. Increased assumed migration levels employed in Series B result in a population of 3.59 million by 2011 for an average annual growth rate of 1.5%. In Series C, which assumes higher volumes of migration, population growth averages 1.6% annually, reaching a total of 3.65 million by 2011.

In the short term, from 1984 to 1986, fertility accounts for population growth while mortality and migration account for the loss in population. Since fertility and migration are particularly age-selective, their effects on the age composition result in an increasing proportion of children (aged 0-14) and a declining proportion of the labour force population (aged 15-64). By 1986, the percentage of children is projected to increase from the 1983 figure of 24.0% to 24.3% (Series A and B) or 24.2% (Series C). The percentage of the labour force population (aged 15-64) is projected to decline from 68.7% in 1983 to a range between 67.9% (Series A) and 68.1% (Series C) by 1986. The percentage of older persons (aged 65+) is expected

to increase, due to population aging, to 7.8% (Series A) or 7.7% (Series B and C) from a level of 7.3% in 1983.

In the long term, migration is projected to regain momentum. The effects of migration and of the general aging of the population are apparent in all the three projection series. The percentage of children (aged 0-14) is expected to decline to 20.3% (Series A, B and C). The labour force population (aged 15-64), is projected to grow to between 70.0% (Series A) and 70.3% (Series C), while older persons (aged 65+) will comprise between 9.4% (Series C) and 9.7% (Series A).

The child dependency ratio (ratio of children 0-14 to the labour force population 15-64) is projected to increase from its 1983 level of 34.9% to 36.4% in 1991 and decline to 29.0% in 2011 according to Series A. A similar pattern is projected for Series B and C. The ratio is projected to increase during 1983-91 and will be 36.3% by 1991 and 28.9% by 2011 according to both series.

The old age dependency ratio (ratio of persons 65+ to the labour force population 15-64) is projected to increase substantially throughout the projection period. By 2011, the old age dependency ratio will reach a range between 13.5% (Series C) and 14.0% (Series A), from a level of 10.6% in 1983.

ASSUMPTIONS

Assumptions on fertility, mortality and migration are used to project births, deaths and net migration.

To project fertility, age specific fertility rates and total fertility rates are used. Recent counts of birth registrations in Alberta show that the number of births has increased from 42,000 in 1981 to 45,000 in 1983. Estimated age specific fertility rates for 1981, 1982 and 1983 also show a

slight increase (Table 2). The total fertility rate for women aged 15-49 has increased from 1989 per thousand women in 1981 to 2006 in 1983. It is assumed that the 1983 fertility rates will be constant throughout the projection period for all three projection series.

The mortality assumption involves the use of the 1981 life table survival ratios by age and sex for Alberta (Table 3). These are assumed to be constant for all three series due to the stability of mortality in recent years.

The three migration assumptions vary both in short-term and long-term levels. The differences are chiefly in the interprovincial component. The short term migration levels are all assumed to be negative. The long term migration levels are assumed to be close to the low migration assumptions used in the previous projection series.

Migration assumption A (low) assumes that the net loss through migration will amount to 34,000 for the year 1983-84. By 1985-86 the loss will decline to 7,300. Net migration is assumed to regain momentum after 1986-87 and will gradually increase to 23,500 per year by 1997 and remain constant at that level thereafter (Table 4).

Migration assumption B (medium) assumes a continuation of loss through net migration in the short-term, at a lesser magnitude than Series A. During 1983-84 net migration loss is projected to be 28,600. This loss will lessen somewhat in the following years. By 1985-86, the volume of net migration loss is assumed to be 3,200. Migration will be positive after 1986, gradually increasing to 25,100 per year by 1996-97, and remaining at that level (Table 5).

Migration assumption C (high) assumes that migration loss during 1983-84 will be 24,700. Net loss through migration will continue in the following year at 5,600. By 1985-86 net migration will gradually pick up and eventually reach 27,000 by 1998-99. After that it is projected to stay constant e at 27,000 annually during the rest of the projection period (Table 6).

Due to the absence of up-to-date information on the age-sex characteristics of migrants, the estimated distributions of net migration by age and sex for the intercensal period 1976-81 was used. These were originally developed using a residual approach applying census survival ratios and life table survival ratios to the census counts. In the current application, they have been adjusted to reduce inconsistencies during the years when Alberta is projected to experience net out-migration. It is also assumed that the age-sex structure of future migrants will be constant during the projection period (Table 7).

GLOSSARY

age-specific fertility rate - the number of births per 1,000 women of a specific age group within the child bearing age range (age 15-49).

child dependency ratio - the ratio of children under 15 to persons between the ages of 15 and 64.

fertility - the contribution of births to population change.

life table - a table of statistics showing the probability of death at each age, the probability of survival to the next age, and other related mortality indicators for a stated population.

life table survival ratios - ratios calculated from the life table, representing the probability of survival from one age group to another.

migration - a permanent change of residence from one geographical unit to another.

mortality - the contribution of deaths to population change.

net migration - the difference between in-migration (including immigration) and out-migration (including emigration) for a geographical unit.

old age dependency ratio - the ratio of persons aged 65 years and over to persons between the ages of 15 and 64.

population growth rate - population growth occurring in a certain period/year divided by the base population at the beginning of that period/year.

projection - a figure for a future date derived from carrying forward assumed trends, which are specifically defined.

total fertility rate - the sum total of age-specific fertility rates.
